

Application Note:

Sol-Ark PCS 200A Pass-Through and CT Placement

Using the 200A Pass-Through and Power Control System (PCS) for Code-Compliant, High-Performance ESS

This application note applies to these Sol-Ark inverters:

Limitless 18K-2P-LV; Limitless 15K-LV; 30K-3P-208V; and 60K-3P-480V

Before engaging in any design or installation of a Distributed Energy Resource (DER) using Sol-Ark products, please familiarize yourself with the installation manual for the specific inverter.

Scope

Practical guidance to design and commission Sol-Ark 15K and Sol-Ark 18K (and larger) inverters with 200 A pass-through, focusing on maximizing Power Control System (PCS) compatibility for whole-home/large-load applications, ESS self-consumption, and code-compliant interconnections—including breaker-fed (load-side) and supply-side (line-side tap) options. Includes current transformer (CT) placement patterns and commissioning checklists.

Note on codes: References align to NEC 2020/2023 Articles 705 (Interconnected Power Production Sources) and 706 (Energy Storage Systems). Requirements vary by AHJ/utility; verify the inverter's listings and local interpretations, especially for NEC 705.13 Power Control Systems (PCS) acceptance.

1. Key Concepts and Capabilities

200 A Pass-Through (Whole-Home)

- Allows the inverter to be placed in-line with a standard 200 A residential service feeder (or ahead of a main load center feeding a house).
- Under grid-present conditions, grid power can pass through to loads; under outage, the inverter/battery supplies loads within its rating.

PCS (Power Control System)

- Uses grid-sense CTs (and internal measurements) to limit export and cap back feed currents dynamically, satisfying utility non-export rules, and enabling NEC 705.13 control schemes where permitted.
- PCS also enables peak-shaving, TOU discharge/charge windows, and self-consumption maximization.

Self-Consumption Optimization

With proper CT placement and settings, the inverter prioritizes serving local loads from PV/battery, importing only deficit power from the grid, and—when export is restricted—trimming PV output/battery discharge to avoid export.

2. Where PCS Unlocks Design Flexibility

Breaker-Fed (Load-Side) Interconnections

- Traditional 120% busbar rule math can severely limit the PV/ESS breaker size (e.g., a 200 A busbar with a 200 A main only allows ~40 A of generation breaker).
- When accepted by the AHJ/utility, NEC 705.13 PCS lets you interconnect with a larger breaker because the system actively controls the net source current, so the panel never exceeds its rating.

Supply-Side (Line-Side Tap) Interconnections

- Useful when the main load center cannot accept additional back-feed or is center-fed.
- A properly sized tap and OCPD feed the inverter upstream of the busbar.
- PCS still controls export at the service point.

Whole-Home 200 A Pass-Through

- Place the inverter between the service disconnect and the main panel to back up the entire building.
- PCS ensures non-export (if required) and keeps service conductors within permitted currents.
- **Design intent:** Use PCS to maximize interconnection size and self-consumption while keeping busbar/service currents within ratings.

3. Quick Math Refresher — 120% Rule versus PCS

3.1 Traditional NEC 705.12(B)(2) 120% Busbar Rule - Load-Side

For a panel with Busbar Rating (B) and Main OCPD (M), the maximum generation breaker (G) without load calculation or PCS is roughly:

$$G_{\text{max}} = 1.2 \times B - M$$

Example: 200 A busbar with 200 A main → $G_{\text{max}} = 240 - 200 = 40$ A. A single 40 A back-feed breaker would be the limit.

3.2 With NEC 705.13 PCS - When Accepted by an AHJ

- The listed PCS monitors and controls total source current so that at the busbar (or service) rating, the sum never exceeds limits (e.g., 200 A).
- Practically, you can land a larger breaker (e.g., 80–125 A, per equipment limits) while configuring PCS to cap export/back-feed so the busbar limit is respected and therefore protected from overloads at all times.
- AHJ/utility acceptance and equipment listing as a PCS are critical—plan reviewers may request a control narrative, settings sheet, and a commissioning test showing the cap works.

4. Typical One-Lines and CT Placement

The golden rule: Grid CTs must “see” the entire service net flow to/from the utility—not just the inverter feeder. Place CTs so the controller acts on the true import/export at the service point.

4.1 Breaker-Fed or Load-Side Interconnection — CTs at Service Conductors

Why CTs here?

They measure whole-home net import/export. PCS then trims inverter power to respect the busbar and export limits.

Panel tips

- Land the inverter breaker at the opposite end of the busbar from the main where required.
- Avoid center-fed busbars for 120% unless the AHJ explicitly allows that method; otherwise, consider supply-side or PCS narrative.

5. CT Hardware and Installation Details

Which conductors?

- Only on the ungrounded (hot) service conductors—never on neutrals/grounds.
- One CT per phase/leg; for split-phase, two CTs; for 3 Φ , three CTs.

Orientation

- Follow the arrow/labeling. A common convention is arrow $\rightarrow$ toward the load, i.e., the grid, for service conductors.
- The inverter UI should indicate positive import versus export; flip a CT if signs are inverted during commissioning.

Location priority

- On service conductors upstream of all load panels (best for global control).
- If impossible, on feeders where all grid exchange is observable (avoid missing sub-feeds like EVSEs or outbuildings that bypass the CTs).

Lead routing

- Keep CT leads away from high-noise cables
- Use twisted pairs where provided
- Respect maximum lead length
- Avoid sharp bends
- Avoid running parallel with inverter AC output for long distances

Verification

- With a known resistive load (such as a 1–2 kW space heater), confirm that the load displays an import of about 1–2 kW.
- With PV/battery discharging, verify a near-zero or capped export per setpoint

6. Maximizing PCS for ESS Self-Consumption and Export Control

6.1 Primary Inverter Settings

- **Mode:** Self-Consumption / Priority Load (serves local loads first).
- **Export Limit:** Zero (non-export) or a specific kW/kVA cap (utility-allowed export).
- **Grid Charge Windows (TOU):** Allow off-peak charge to raise SoC for on-peak discharge/peak shaving.
- **SoC Reserves:** Maintain UPS reserve for outages (e.g., 20–40%) while still enabling peak shaving above that.

6.2 “Exceed 120%” on a Breaker-Fed Tie Using PCS

1. Choose a larger inverter breaker appropriate to conductor/equipment limits (e.g., 80–125 A for a 15K-class AC output—use manufacturer tables).
2. Set the PCS export cap so that $\text{Main OCPD} + \text{Effective Back-feed} \leq \text{Busbar Rating}$ at all times.
3. Document the control narrative in the plan set: where CTs are, the exact limit value, and the witness test you will perform.
4. During commissioning, you can confirm the cap with a clamp meter and UI screenshots.

Example

Consider this scenario:

- 200 A busbar, 200 A main, inverter landed on a 100 A breaker.
- Traditional 120% would limit you to 40 A; with PCS, set an export cap so the net back-feed never raises busbar current >200 A.

6.3 TOU and Demand-Charge Playbook

- **Off-peak:** Allow limited grid charge to target an SoC that covers expected on-peak demand.
- **On-peak:** Enforce zero-export (if required) but allow full discharge to shave grid import to a target (e.g., 2–3 kW net).
- **Shoulder:** Float at self-consumption; backstop with small import cap for comfort loads (HVAC/EVSE coordination helps).

7. Breaker-Fed versus Line-Side Tap

Consideration	Break-Fed (Load Side)	Supply Side (Line-Side Tap)
Panel Constraints	Limited by 120% unless PCS accepted	Bypasses busbar calc; tap rules apply
AHJ Comfort	High (familiar), but center-fed busbars tricky	Varies; needs service-rated gear, labeling
Metering/Utility	Standard net meter/non-export meter	Utility may require separate service disconnect
PCS Value	Enables larger breaker under 705.13	Controls export at service point

8. Parallel Inverters and 3-Phase Notes

Stacked/Parallel Sol-Ark

- Use the designated CT input architecture per manual (one shared grid-CT)

Three-Phase (30K/60K)

- One CT per phase (A/B/C).
- Confirm phase mapping in software so CT-phase matches voltage phase.
- Run loads one phase at a time to validate proper that CTs are on the correct phase and are oriented properly.
- On three-phase services, the arrows on the CT should point to the inverter.

9. Common Problems and Quick Fixes

- **PCS blind to house loads** → CTs on the wrong conductors (e.g., only on inverter feeder) → Move CTs to service conductors.
- **Export shows as import** → Reversed CT polarity → Flip CT orientation.
- **Generator back feed risk** → Never allow export toward a generator; use approved transfer/ATS → Place CTs on the load conductors, not generator or utility conductors.

10. Boilerplate Plan-Set Editable

Below is an editable form you can fill out and include with the plan-set that you submit to an AHJ to illustrate the interconnection means of the DER project.

Interconnection Method

☐ Load-Side (Breaker-Fed) ☐ Supply-Side (Line-Side Tap)

Busbar/Main Ratings

Bus ____ A, Main ____ A; Inverter AC OCPD ____ A; Conductors ____ AWG Cu/Al (____ °C)

PCS Declaration (NEC 705.13)

This system employs a listed power control function in the Sol-Ark inverter to maintain total source current at or below ____ A at the [panel/service] at all times.

Control is based on service-conductor CTs located at ____.

Export limit set to ____ kW.

Commissioning Test

Zero-export and export-cap witness tests will be performed; screenshots and clamp-meter photos provided to AHJ.
